

Altera SoC FPGA-Adaptive Debug

Introduction

By integrating processor, peripherals and FPGA into a single chip, SoC FPGAs can make faster, less expensive and more energy-efficient products possible. This innovation in hardware, however, must be matched with support in software development and debug tools to bring these features to life.

In their 2014 Embedded Market Study, UBM and EETIMES found that “*Meeting schedules* remains the premier challenge for development with the *debugging process*... not far behind.” Indeed, the debugging process can present one of the longest development phases. Any tool that speeds up debug in order to meet schedules is of high value. One challenging phase in the debug process is that of optimizing performance and power, without ripping apart ones’ design.

This Architecture Brief describes how the Altera SoC Embedded Design Suite (EDS) toolset, which includes the ARM® Development Studio 5 (DS-5™) Altera Edition Toolkit, can be used to quickly and confidently debug an Altera SoC FPGA.

At the center is FPGA-Adaptive Debug capability.

Key aspects of this Architecture Brief are highlighted in two videos from ARMflix:

- “FPGA-Adaptive Debug on the Altera SoC using ARM DS-5”
(<http://www.youtube.com/watch?v=2NBcUv2Txbl>)
- “DS-5 Altera Edition: FPGA-adaptive Linux Kernel Debug and Trace”
(<http://www.youtube.com/watch?v=lrR-SfVZd18>)

Development Tool Challenges

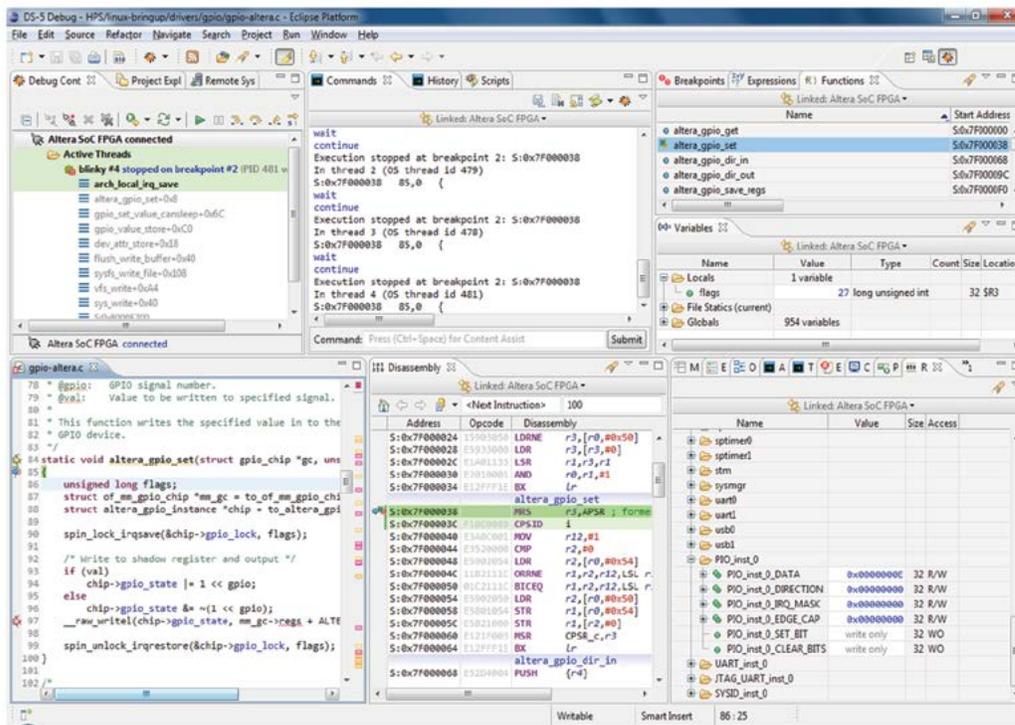

Programmability of the FPGA means that engineers might re-program the hardware during the course of the development project; hardware can even be re-configured during runtime. This has two important software implications:

1. The CPU software and the FPGA programs must be developed and debugged alongside each other; in a traditional SoC, the embedded software is developed on top of fixed hardware.
2. The FPGA hardware definition is user-defined, therefore the software development tools and board support packages (BSPs) that ship with the SoC FPGAs will support all the standard peripherals, but they are not pre-loaded with any memory map information or debugging hooks for the FPGA-based peripherals the hardware team may create.

ARM DS-5 Altera Edition Tool Kit

To support the unique advantages and features of Altera SoC FPGAs without requiring a new set of vendor-proprietary tools, Altera teamed with industry leader ARM to develop a special edition of the industry-standard ARM DS-5™ Toolkit to support Altera SoC FPGAs. The ARM DS-5 Altera Edition Toolkit, offers FPGA-adaptive debug and other key multicore features using the familiar, industry-standard ARM DS-5 interface (*Figure 1*). The package also enables the use of a single Altera USB-Blaster™ II cable for both hardware and software debug.

Figure 1: The ARM DS-5™ Altera Edition Toolkit Interface is Already Familiar to Many ARM Developers

ARM Compatibility a Given; FPGA Implementation a Difference

All the SoC FPGAs currently on the market leverage ARM processor IP, which generally includes support from the vast ecosystem for ARM processor software development tools. First and foremost, it is critical that the tools for these new devices be ARM-compatible and leverage the ARM ecosystem. However, each vendor deals differently with the added dimension of the FPGA portion of the device. This particularly impacts the following:

Whole-Chip Debug

With SoC FPGAs, the SoC is no longer pre-defined, and the debugging tools must support a number of new constructs, namely:

- Adapt to changing user-defined peripherals implemented in the FPGA
- Test software functions that include hardware acceleration blocks implemented in the FPGA
- Debug custom logic blocks in the FPGA that implement proprietary algorithms

Traditional software debugging tools were not designed for fluctuating hardware functions, and traditional FPGA tools have no 'hooks' back to the software tools. To bridge this debugging chasm, a toolset must provide:

- Whole-chip visibility of both the processor and the FPGA subsystems
- Cross-triggering and in-system trace between CPU and FPGA subsystem
- System-wide monitoring for software, CPU hardware, and FPGA hardware events
- Performance profiling

Ideally, the debugging tool should be as flexible as the FPGA. This vision is called 'FPGA-adaptive debugging', and it has become a reality with the Altera SoC FPGA development flow.

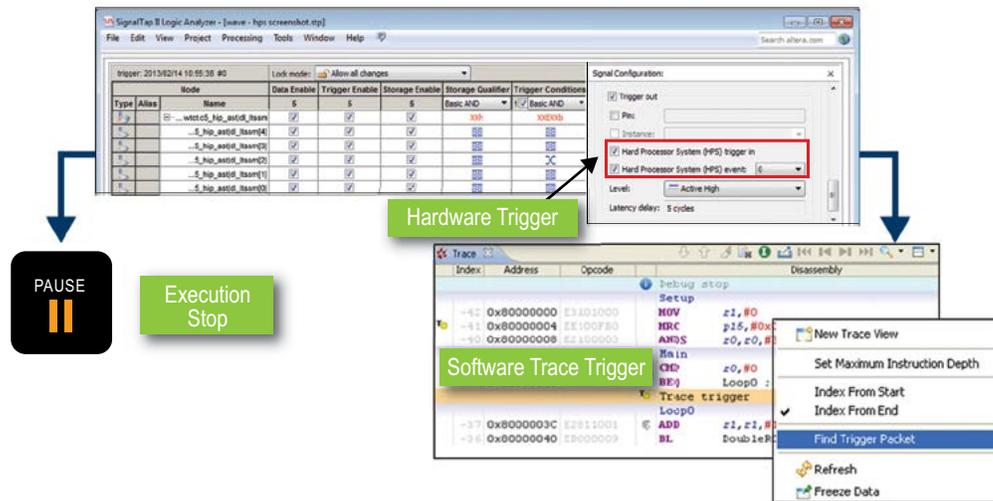

FPGA-adaptive debugging means that software debug tools automatically adapt to changes in the hardware due to changes in the FPGA logic. As the hardware engineer iterates through various FPGA configurations, the software debug view updates automatically, with all FPGA-based peripherals automatically appearing in the register view.

CoreSight Compliant Cross-Triggering

Finding the cause of a bug is much easier if the processor subsystem and FPGA subsystem can cross-trigger from code to waveform, or from waveform to code, enabling the development team to find and track how and why a particular condition occurred in the system. **Figure 2** shows a cross-triggering example from the ARM Development Studio-5 (DS-5™) Altera Edition Toolkit software. When coupled with waveform views from the Altera SignalTap™ II Logic Analyzer, cross-triggering, trace, and global time-stamping are valuable features for IP verification, custom driver development, and the system integration portion of a project.

Though various debug tools and associated cables are available for the ARM processor and FPGA fabric, it can be difficult to manage two separate debugging frameworks at a system level. Correlating events becomes next to impossible. Most developers prefer a single (and low-cost) JTAG cable that supports both hardware targets (the FPGA and the CPU subsystem). Using one cable and a commonly-understood software interface provides an efficient, easy-to-use means for driver developers, board engineers and FPGA designers to work together to bring up the entire system.

Figure 2: Cross-triggering from the hardware world to the software world

Besides finding the location of fault, it is also valuable to find out exactly how and why the system entered the faulty state. The ARM CoreSight™ System Trace Module (STM) contained in Altera SoC FPGAs enables tracking of CPU-based software events as well as user-defined system level states such as 'low power mode' or 'high performance mode'. The application software can issue hardware and software event "bread crumbs" as the system executes over time to monitor system behavior. In an FPGA-adaptive debugging environment, the STM enables event monitoring in both the CPU and FPGA domains without stopping the system or affecting execution performance.

Multicore Debug

As the embedded world moves to multicore, development tools must follow suit. Developing software for multicore platforms is more complicated than single core. Choosing on which core to set a breakpoint; determining on which core the software is running at any particular time becomes critical for multicore debug.

It is essential to be able to control and monitor the cores simultaneously as well as independently. In some cases it may be necessary to stop both cores on a breakpoint; but in others, it may be preferable to let one core keep running on a breakpoint, too. It is also valuable to have visibility to the software running on each core. Ideally a debugger and analysis tools, both built from the ground-up for multicore systems, should be used.

GNU tools were designed in the single-core era; the GNU Debugger (GDB) works well, but only on a single core at a time. When using a GDB-based debugger on a multicore system, breakpoints can be set up across multiple cores. When software hits a breakpoint, only the core where the breakpoint occurred can be viewed during the debug session, which is extremely limiting for multicore debugging.

Table 1: In-System Debugging and Development Tool Features for SoC FPGA Devices

Function/Feature	Altera SoC EDS (with ARM DS-5 Altera Edition)	Vendor B's Debug Tools
Versions Compared	13.1	2013.3
FPGA-Adaptive Debugging	Yes	No
All ARM Processor and FPGA Tools Operate Over Single USB Cable	Yes	No
Auto Display of Peripheral Registers	Yes	No
Display of VFP and Neon Registers	Yes	No
Debug: Single-Step, Watchpoints, etc.	Yes	Yes
CPU ↔ FPGA CoreSight Compliant Cross-Triggering	Yes	No Vendor proprietary
CPU ↔ FPGA Cross-Triggering with Timestamps and Trace Data Stream	Yes ARM CoreSight™ compliant using System Trace Macrocell (STM)	No Available with purchase of additional third-party hardware and software
Processor Trace Support	Yes	No Requires additional 3rd-party hardware and software
Trace Buffer	32 KB	4 KB
Route Trace Packets to Alternative Destinations (e.g. DRAM or high-speed transceiver)	Yes Coresight Embedded Trace Router	No
Route Trace Packets to External Trace Probe	Yes	Yes
FPGA Information Included in ARM Trace Stream	Yes Uses ARM CoreSight System Trace Macrocell	Yes Vendor proprietary solution
Native Linux Support for Hardware-Assisted Trace	Yes Kernel and Application	No
Concurrent Multicore Debugger	Yes ARM DS-5 Specifically designed for multicore systems	No
Multicore Debugging in Asymmetric Multiprocessing (AMP) Applications	Yes	Yes
Multicore Debugging with Symmetric Multiprocessing (SMP) Operating Systems	Yes	No
Linux Kernel Awareness	Yes	No
Code Profiling	Yes ARM Streamline including processor, FPGA, and power profiling. No instrumentation required	No
Semi-Hosting Support (communication between host and ARM processors over JTAG)	Yes	No
FPGA Logic Analyzer	SignalTap II Logic Analyzer	Yes
Bare-Metal Application Development	Modifiable hardware libraries with friendly, open BSD licensing	Vendor proprietary BSP project build
Hardware VFP and NEON Compiler Support	Yes (Linux) Support for Bare Metal compiler available in version 14.0	Yes (Linux/Bare Metal)

Conclusion

To provide hardware and software teams the tools they need, and to keep projects on schedule and on budget, the right in-system debugging tool is critical. This Architecture Brief described how the Altera solution based on the ARM DS-5 Altera Edition Toolkit offers simultaneous insight and control into both the ARM processor and FPGA logic portions of the SoC FPGA, enabling project teams to implement advanced features in these new devices while keeping schedules on track.
