**Intel® Stratix® 10 Device Design Guidelines**

This document provides a set of design guidelines, recommendations, and a list of factors to consider for designs that use Intel® Stratix® 10 FPGAs. It is important to follow Intel recommendations throughout the design process for high-density, high-performance Intel Stratix 10 designs. This document also assists you with planning the FPGA and system early in the design process, which is crucial to successfully meet design requirements.

**Note:** This document does not include all Intel Stratix 10 device details and features. For more information about Intel Stratix 10 devices and features, refer to the respective Intel Stratix 10 User Guides.

The material references the Intel Stratix 10 device architecture as well as aspects of the Intel Quartus® Prime software and third-party tools that you might use in your design. The guidelines presented in this document can improve productivity and avoid common design pitfalls.

**System Specification**

In systems that contain an Intel Stratix 10 device, the FPGA typically plays a large role in the overall system and affects the rest of the system design. It is important to start the design process by creating detailed design specifications for the system and the FPGA, and determining the FPGA input and output interfaces to the rest of the system.
Design Specifications

<td>Plan clock resources and I/O interfaces early with a block diagram.</td>
</tr>
</tbody>
</table>

Create detailed design specifications that define the system before you create your logic design or complete your system design, by performing the following:

- Specify the I/O interfaces for the FPGA
- Identify the different clock domains
- Include a block diagram of basic design functions
- Include intellectual property (IP) blocks

*Note:* Taking the time to create these specifications improves design efficiency, but this stage is often skipped by FPGA designers.

- Create a functional verification/test plan
- Consider a common design directory structure

Create a functional verification plan to ensure the team knows how to verify the system. Creating a test plan at this stage can also help you design for testability and design for manufacturability. For example, do you want to perform built-in-self test (BIST) functions to drive interfaces? If so, you could use a UART interface with a Nios® processor inside the FPGA device. You might require the ability to validate all the design interfaces.

If your design includes multiple designers, it is useful to consider a common design directory structure. This eases the design integration stages.

Intel and its third-party IP partners offer a large selection of off-the-shelf IP cores optimized for Intel devices. You can easily implement these parameterized blocks of IP in your design, reducing your system implementation and verification time, and allowing you to concentrate on adding proprietary value.
IP selection often affects system design, especially if the FPGA interfaces with other devices in the system. Consider which I/O interfaces or other blocks in your system design can be implemented using IP cores, and plan to incorporate these cores in your FPGA design.

The Intel FPGA IP Evaluation Mode feature available for many IP cores allows you to program the FPGA to verify your design in hardware before you purchase the IP license. The evaluation supports an untethered mode, in which the design runs for a limited time, or a tethered mode. The tethered mode requires an Intel serial JTAG cable connected between the JTAG port on your board and a host computer running the Intel Quartus Prime Programmer for the duration of the hardware evaluation period.

Platform Designer is a system integration tool included as part of the Intel Quartus Prime software. Platform Designer captures system-level hardware designs at a high level of abstraction and automates the task of defining and integrating customized Hardware Description Language (HDL) components. These components include IP cores, verification IP, and other design modules. Platform Designer facilitates design reuse by packaging and integrating your custom components with Intel and third-party IP components. Platform Designer automatically creates interconnect logic from the high-level connectivity you specify, thereby eliminating the error-prone and time-consuming task of writing HDL to specify system-level connections.

Platform Designer is more powerful if you design your custom components using standard interfaces. By using standard interfaces, your components inter-operate with the components in the Platform Designer Library. In addition, you can take advantage of bus functional models (BFMs), monitors, and other verification IP to verify your design.

</tbody>
</table>

Intel Stratix 10 devices offer a range of densities that provide different amounts of device logic resources, including memory, multipliers, and adaptive logic module (ALM) logic cells. Determining the required logic density can be a challenging part of the design planning process. Devices with more logic resources can implement larger and potentially more complex designs, but generally have a higher cost. Smaller devices have lower static power utilization. Intel Stratix 10 devices support vertical migration, which provides flexibility.
You may observe 10% – 15% increase in resource utilization when you migrate your design from existing devices to Intel Stratix 10 devices. Review the resource utilization to find out which device density fits the design. Consider that the coding style, device architecture, and optimization options used in the Intel Quartus Prime software can significantly affect a design’s resource utilization and timing performance.

Select a device that meets your design requirements with some safety margin in case you want to add more logic later in the design cycle, upgrade, or expand your design. You might also want additional space in the device to ease design floorplan creation for an incremental or team-based design. Consider reserving resources for debugging.

### I/O Pin Count, LVDS Channels, and Package Offering

<tr>
<td>3</td>
<td></td>
<td>Verify that the number of LVDS channels are enough.</td>
</tr>
</tbody>
</table>

Determine the required number of I/O pins for your application, considering the design’s interface requirements with other system blocks.

Larger densities and package pin counts offer more full-duplex LVDS channels for different signaling; ensure that your device density-package combination includes enough LVDS channels. Other factors can also affect the number of I/O pins required for a design, including simultaneous switching noise (SSN) concerns, pin placement guidelines, pins used as dedicated inputs, I/O standard availability for each I/O bank, differences between I/O standards and speed for row and column I/O banks, and package migration options.

You can compile any existing designs in the Intel Quartus Prime software to determine how many I/O pins are used. Also consider reserving I/O pins for debugging.

### Speed Grade

<tr>
<td>1</td>
<td></td>
<td>Determine the device speed grade that you require.</td>
</tr>
</tbody>
</table>

The device speed grade affects the device timing performance and timing closure, as well as power utilization. One way to determine which speed grade your design requires is to consider the supported clock rates for specific I/O interfaces.

You can use the fastest speed grade during prototyping to reduce compilation time (because less time is spent optimizing the design to meet timing requirements), and then move to a slower speed grade for production to reduce cost if the design meets its timing requirements.

</tr>
<tr>
<td>2</td>
<td></td>
<td>Refer to the External Memory Interfaces Intel Stratix 10 FPGA IP User Guide for the external memory interface (EMIF) pin pairing.</td>
</tr>
</tbody>
</table>
Intel Stratix 10 devices support vertical migration within the same package, which enables you to migrate to different density devices whose dedicated input pins, configuration pins, and power pins are the same for a given package. This feature allows future upgrades or changes to your design without any changes to the board layout, because you can replace the FPGA on the board with a different density Intel Stratix 10 device.

Determine whether you want the option of migrating your design to another device density. Choose your device density and package to accommodate any possible future device migration to allow flexibility when the design nears completion. You should specify any potential migration options in the Intel Quartus Prime software at the beginning of your design cycle or as soon as the device migration selection is possible in the Intel Quartus Prime software. Selecting a migration device can impact the design’s pin placement, because the Fitter ensures your design is compatible with the selected devices. It is possible to add migration devices later in the design cycle, but it requires extra effort to check pin assignments, and can require design or board layout changes to fit into the new target device. It is easier to consider these issues early in the design cycle than at the end, when the design is near completion and ready for migration.

The Intel Quartus Prime Pin Planner highlights pins that change function in the migration device when compared to the currently selected device.

Early System and Board Planning

System information related to the FPGA should be planned early in the design process, before designers have completed the design in the Intel Quartus Prime software. Early planning allows the FPGA team to provide early information to PCB board and system designers.

Early Power Estimation

<table>
<thead>
<tr>
<th>Table 11. Early Power Estimation Checklist</th>

</thead>
<tbody>
<tr>
<td><strong>Number</strong></td>

<tr>
<td>1</td>
</tr>
</tbody>
</table>
FPGA power consumption is an important design consideration and must be estimated accurately to develop an appropriate power budget to design the power supplies, voltage regulators, decouplers, heat sink, and cooling system. Power estimation and analysis have two significant planning requirements:

- **Thermal planning**—The cooling solution must sufficiently dissipate the heat generated by the device. In particular, the computed junction temperature must fall within normal device specifications.
- **Power supply planning**—The power supplies must provide adequate current to support device operation.

Power consumption in FPGA devices is dependent on the logic design. This dependence can make power estimation challenging during the early board specification and layout stages. The Intel EPE tool allows you to estimate power utilization before the design is complete by processing information about the device and the device resources that will be used in the design, as well as the operating frequency, toggle rates, and environmental considerations. You can use the tool to obtain thermal design parameters, with which you can perform detailed thermal simulation and cooling solution design.

If you do not have an existing design, estimate the number of device resources used in your design and enter it manually. The EPE tool accuracy depends on your inputs and your estimation of the device resources. If this information changes (during or after your design is complete), your power estimation results are less accurate. If you have an existing design or a partially-completed compiled design, use the Generate Early Power Estimator File command in the Intel Quartus Prime software to provide input to the spreadsheet.

The EPE spreadsheet includes the Import Data macro, which parses the information in the Intel Quartus Prime-generated power estimation file (.csv), or alternatively from an older version of the EPE, and transfers it into the EPE tool. If you do not want to use the macro, you can transfer the data into the EPE tool manually. You should enter additional resources to be used in the final design manually if the existing Intel Quartus Prime project represents only a portion of your full design. You can edit the inputs to the EPE tool and add additional device resources or adjust the parameters after importing the power estimation file information.

When the design is complete, the Power Analyzer tool in the Intel Quartus Prime software provides more accurate estimation of power, ensuring that thermal and supply budgets are not violated. For the most accurate power estimation, use gate-level simulation results with an output file (.vcd) from a third-party simulation tool.

</tbody>
</table>

Intel Stratix 10 is a multi-chip module, depending on package configuration and design information, power distribution on all dies can be quite different. This feature makes the Intel Stratix 10 thermal characteristics design dependent. EPE takes into consideration of your design input, and generates unique thermal parameters for your design in the Thermal Page. You can get power consumption for each die, thermal resistance for all dies ($\psi_{JC}$), cooling solution requirement ($\psi_{CA}$), and maximum allowed package case temperature ($T_{case}$).

The thermal analysis of the Intel Stratix 10 device requires you use a Compact Thermal Model (contact your local Intel representatives to obtain the model) and perform simulation in a Computational Fluid Dynamics (CFD) tool. The result of the CFD analysis gives the $T_{case}$ which should be lower than the required value in the EPE Thermal Page. With the simulated $T_{case}$, $\psi_{JC}$, and total package power, you can obtain the actual junction temperature $T_J$, which needs to stay below your requirement, for example, 95°C. You can adjust your cooling solution (heat sink design, airflow, and so on) to optimize your thermal design.

</tr>
</tbody>
</table>

Intel Stratix 10 devices have internal and external temperature sensing capabilities. You can measure the junction temperature, $T_J$, with the following methods:
- Using internal TSD by instantiating the Temperature Sensor Intel Stratix 10 FPGA IP core.
- Using external thermal diode designed to interface with third-party sensor chip. Ensure the third-party sensor chip matches the external TSD specifications as documented in the Intel Stratix 10 Device Datasheet.
Monitoring the actual junction temperature is crucial for thermal management. Intel Stratix 10 devices include TSD on each die with embedded analog-to-digital converter (ADC) circuitry. You can access the digital temperature readout through the Temperature Sensor IP core.

The Intel Stratix 10 TSD can self-monitor the device junction temperature and can be used with external circuitry for activities such as controlling air flow to the FPGA. This requires including the TSD circuitry by instantiating a Temperature Sensor IP core.

The flexibility in Intel Stratix 10 design can lead to non-uniform power distribution on transceiver dies. Therefore, the hotspot on the transceiver dies may not necessarily be at the TSD location. This results in a temperature difference between TSD readout and real junction temperature. EPE calculates this difference and reports an offset value for each TSD. You need to add the offset values to your TSD reading to get the actual junction temperature.

Intel Stratix 10 devices are based on SRAM cells. You must download configuration data to the Intel Stratix 10 device each time the device powers up, because SRAM is volatile. Consider whether you require multiple configuration schemes, such as one for debugging or testing and another for the production environment.
Choosing the device configuration method early allows system and board designers to determine what companion devices, if any, are required for the system. Your board layout also depends on the configuration method you plan to use for the programmable device, because different schemes require different connections.

In addition, Intel Stratix 10 devices offer advanced configuration features, depending on your configuration scheme. Intel Stratix 10 devices also include optional configuration pins and a reconfiguration option that you should choose early in the design process (and set up in the Intel Quartus Prime software), so you have all the information required for your board and system design.

Intel Stratix 10 devices offer several configuration schemes.

You can enable any specific configuration scheme by driving the Intel Stratix 10 device MSEL pins to specific values on the board.

All configuration schemes use a configuration device, a download cable, or an external controller (for example, MAX® (MAX II, MAX V, Intel MAX 10) devices or a microprocessor).

Intel low-voltage quad-serial configuration (EPCQ-L) devices are used in the AS configuration scheme.

Serial configuration devices can be programmed using a Intel FPGA Download Cable II or Intel FPGA Ethernet Cable II download cable with the Intel Quartus Prime software through the active serial interface.

Alternatively, you can use supported third-party programmers such as BP Microsystems and System General, or a microprocessor with the SRunner software driver. SRunner is a software driver developed for embedded serial configuration device programming that designers can customize to fit in different embedded systems.

Serial configuration devices do not directly support the JTAG interface; however, you can program the device with JTAG download cables using the Intel Stratix 10 FPGA as a bridge between the JTAG interface and the configuration device, allowing both devices to use the same JTAG interface.

Programming the EPCQ-L from JTAG using the Intel Stratix 10 FPGA as a bridge is slower than using the standard AS interface.

The Intel Quartus Prime programmer supports configuration of the Intel Stratix 10 devices directly using JTAG interfaces with Intel programming download cables. You can download design changes directly to the device with Intel download cables, making prototyping easy and enabling you to make multiple design iterations in quick succession. You can use the same download cable to program configuration devices on the board and use JTAG debugging tools such as the Signal Tap Embedded Logic Analyzer.

<td>Ensure your configuration scheme and board support the required features: design security, remote upgrades, single event upset (SEU) mitigation.</td>

This section describes Intel Stratix 10 configuration features and how they affect your design process.

**Configuration Bitstream Compression**

Configuration bitstream compression is always enabled in Intel Stratix 10 configuration. The Intel Quartus Prime software generates configuration files with compressed configuration data. This compressed file reduces the storage requirements in the configuration device or flash memory, and decreases the time required to transmit the configuration bitstream to the Intel Stratix 10 device.

Due to compressed configuration bitstream, passive configuration schemes for example Avalon®-ST ×8, ×16, and ×32 might require the external configuration host to pause sending configuration data by deasserting the AVST_READY signal.

**Design Security Using Configuration Bitstream Encryption**

The design security feature ensures that Intel Stratix 10 designs are protected from copying, reverse engineering, and tampering. Intel Stratix 10 devices have the ability to decrypt configuration bitstreams using the AES algorithm, an industry standard encryption algorithm that is FIPS-197 certified. Intel Stratix 10 devices have a design security feature which utilizes a 256-bit security key.

The design security feature is available in the all configuration schemes supported in the Intel Stratix 10 devices.

**SEU Mitigation**

Dedicated circuitry is built into Intel Stratix 10 devices for error detection and correction. When enabled, this feature checks for SEUs continuously and automatically. This allows you to confirm that the configuration data stored in an Intel Stratix 10 device is correct and alerts the system to a configuration error.

When using the SEU mitigation features, an SDM pin is used to implement the SEU_ERROR function. This pin flags errors for your system to take appropriate actions. Prior to compiling your design, enable the SEU_ERROR function and select an unused SDM pin to implement the SEU_ERROR function in the Intel Quartus Prime software.

Planning for On-Chip Debugging

On-chip debugging is an optional step in the design flow, and different debugging tools work better for different systems and different designers. Evaluate on-chip debugging options early in your design process to ensure that your system board, Intel Quartus Prime project, and design are able to support the appropriate options. Planning can reduce time spent debugging, and eliminates design changes later to accommodate your preferred debugging methodologies. Adding debug pins might not be enough, because of internal signal accessibility and I/O pin accessibility on the device. First, select your preferred debugging tools.

</tbody>
</table>

The Intel Quartus Prime portfolio of verification tools includes the following in-system debugging features:

- **Signal Probe incremental routing**—Quickly routes internal signals to I/O pins without affecting the routing of the original design. Starting with a fully routed design, you can select and route signals for debugging to either previously reserved or currently unused I/O pins.

- **Signal Tap Embedded Logic Analyzer**—Probes the state of internal and I/O signals without the use of external equipment or extra I/O pins, while the design is running at full speed in an FPGA device. Defining custom trigger-condition logic provides greater accuracy and improves the ability to isolate problems. It does not require external probes or changes to the design files to capture the state of the internal nodes or I/O pins in the design; all captured signal data is stored in the device memory until you are ready to read and analyze the data. The Signal Tap Embedded Logic Analyzer works best for synchronous interfaces. For debugging asynchronous interfaces, consider using Signal Probe or an external logic analyzer to view the signals more accurately. Signal Tap may affect routing of the original design.

- **Logic Analyzer Interface**—Enables you to connect and transmit internal FPGA signals to an external logic analyzer for analysis, allowing you to take advantage of advanced features in your external logic analyzer or mixed signal oscilloscope. You can use this feature to connect a large set of internal device signals to a small number of output pins for debugging purposes and it can multiplex signals with design I/O pins if required.
• In-System Memory Content Editor—Provides read and write access to in-system FPGA memories and constants through the JTAG interface, so you can test changes to memory content and constant values in the FPGA while the device is functioning in the system.

• In-System Sources and Probes—Sets up custom register chains to drive or sample the instrumented nodes in your logic design, providing an easy way to input simple virtual stimuli and capture the current value of instrumented nodes.

• Virtual JTAG Intel FPGA IP core—Enables you to build your own system-level debugging infrastructure, including both processor-based debugging solutions and debugging tools in the software for system-level debugging. You can instantiate the SLD_VIRTUAL_JTAG Intel FPGA IP core directly in your HDL code to provide one or more transparent communication channels to access parts of your FPGA design using the JTAG interface of the device.

• EMIF Debug toolkit—Tcl-based graphical user interface communicating via a JTAG connection to enable external memory interface on the circuit board to retrieve calibration status and debug information. The Driver Margining feature of the tool kit allows you to measure margins on your memory interface using a driver with arbitrary traffic patterns. Tcl-based graphical user interface that provides access to memory calibration data gathered by the Nios II sequencer, via a JTAG connection. The Toolkit allows you to mask ranks for calibration, and to request recalibration of the interface. The Driver Margining feature of the toolkit allows you to measure margins on the memory interface using a driver with arbitrary traffic patterns. The EMIF Toolkit can communicate with several different memory interfaces on the same device, but only one at a time.

• Transceiver Toolkit—Uses System Console technology to help FPGA and board designers validate transceiver link signal integrity real time in a system and improve board bring-up time. Test for bit-error rate (BER) while simultaneously running multiple links at your target data rate to validate your board design with Transceiver Toolkit. Tune transceiver analog settings for optimal link performance while using different test metrics to quantify results. Simultaneously test multiple devices across one or more boards using link tests in the Transceiver Toolkit GUI.

<td></td>
<td>Design power sequencing and voltage regulators for best device reliability. Connect the GND between boards before connecting the power supplies.</td>
</tr>
</tbody>
</table>

The minimum current requirement for the power-on-reset (POR) supplies must be available during device power-up.
The Intel Stratix 10 device has Power-On Reset Circuitry, which keeps the device in a reset state until the power supply outputs are within the recommended operating range. The device must reach the recommended operating range within the maximum power supply ramp time. If the ramp time is not met, the device I/O pins and programming registers remain tri-stated and device configuration fails. For the Intel Stratix 10 device to exit POR, you must power the $V_{CCBAT}$ power supply even if you do not use the volatile key.

In Intel Stratix 10 devices, a pin-selectable option (MSEL) allows you to select between a typical POR time setting of 4 ms or 100 ms. In both cases, you can extend the POR time by using an external component to assert the $nSTATUS$ pin low. Extend POR time if the board cannot meet the maximum power ramp time specifications to ensure the device configures properly and enters user mode.

Intel Stratix 10 devices have power-up sequencing and power-down sequencing requirements. You should consider the power-up timing and power-down timing for each rail in order to meet the power sequencing requirements.

Intel uses GND as a reference for I/O buffer designs. Connecting the GND between boards before connecting the power supplies prevents the GND on your board from being pulled up inadvertently by a path to power through other components on your board. A pulled-up GND could otherwise cause an out-of-specification I/O voltage or current condition with the Intel device.

</tr>
</tbody>
</table>

Intel Stratix 10 devices require various voltage supplies depending on your design requirements.

Intel Stratix 10 devices support a wide range of industry I/O standards. The device output pins do not meet the I/O standard specifications if the $V_{CCIO}$ level is out of the recommended operating range for the I/O standard.

Voltage reference ($V_{REF}$) pins serve as voltage references for certain I/O standards. The $V_{REF}$ pin is used mainly for a voltage bias and does not source or sink much current. The voltage can be created with a regulator or a resistor divider network.
The \texttt{VREFP\_ADC} pin is not a power supply pin. It provides the reference voltage for the ADC for the voltage sensor. For better voltage sensor performance, connect the \texttt{VREFP\_ADC} pin to an external reference 1.25 V source. Connecting the \texttt{VREFP\_ADC} pin to GND actives an on-chip reference source.

<tr>
<td>1</td>
<td></td>
<td>Use the PDN tool to plan your power distribution netlist and decoupling capacitors.</td>
</tr>
</tbody>
</table>

Board decoupling is important for improving overall power supply integrity while ensuring the rated device performance.

Intel Stratix 10 devices include on-die decoupling capacitors to provide high-frequency decoupling. These low-inductance capacitors suppress power noise for excellent power integrity performance, and reduce the number of external PCB decoupling capacitors, saving board space, reducing cost, and greatly simplifying PCB design.

Intel has created an easy-to-use power distribution network (PDN) design tool that optimizes the board-level PDN graphically. The purpose of the board-level PDN is to distribute power and return currents from the voltage regulating module (VRM) to the FPGA power supplies. By using the PDN tool, you can quickly arrive at an optimized PDN decoupling solution for your specific design.

For each power supply, PDN designers must choose a network of bulk and decoupling capacitors. While SPICE simulation could be used to simulate the circuit, the PDN design tool provides a fast, accurate, and interactive way to determine the right number of decoupling capacitors for optimal cost and performance trade-offs.

<td>Ensure ( V_{\text{CCIO}<em>{\text{SDM}}} ) and ( V</em>{\text{CCIO}} ) of the configuration pins match the voltage level of the external devices used for configuration.</td>
</tr>
</tbody>
</table>

Configuration pins from the Intel Stratix 10 device connect to external devices, for example the EPCQ-L configuration device, Avalon-ST host, or SD/MMC flash memories. The voltage level of the configuration pins need to match the voltage level of the devices connected to them. The JTAG and SDM I/Os used as configuration pins are powered by the \( V_{\text{CCIO}_{\text{SDM}}} \) supply. For Avalon-ST \( \times 32 \) and \( \times 16 \) configuration schemes, the \( \text{AVST}_{\text{CLK}}, \text{AVST}_{\text{VALID}}, \text{and AVST}_{\text{DATA}} \) pins are powered by the \( V_{\text{CCIO}} \) of the I/O bank in which the pins reside in. When using the Avalon-ST \( \times 32 \) or \( \times 16 \) configuration scheme, \( V_{\text{CCIO}} \) of the I/O bank which the \( \text{AVST}_{\text{CLK}}, \text{AVST}_{\text{VALID}}, \) and \( \text{AVST}_{\text{DATA}} \) pins are located in, must match the \( V_{\text{CCIO}_{\text{SDM}}} \) level.

Board trace for clocks used in configuration, for example \( \text{TCK}, \text{AS}_{\text{CLK}}, \text{AVST}_{\text{x8}_{\text{CLK}}}, \text{AVST}_{\text{CLK}}, \text{SDMMC}_{\text{CFG}_{\text{CCLK}}}, \) and \( \text{OSC}_{\text{CLK}}_{\text{1}} \) clock input, should produce clean signals with no overshoot, undershoot, or ringing. When designing the board, lay out the configuration clock traces with the same techniques used to lay out a clock line. Any overshoot, undershoot, ringing, or other noise on the clock signal can cause configuration failure. Make sure to have clock routing as stripline. Keep the clock routing away from any high-speed signals to isolate the clock signals from other signals.

### JTAG Pins

Because JTAG configuration takes precedence over all other configuration methods, the JTAG pins should not be left floating or toggling during configuration if you do not use the JTAG interface. If you are using the JTAG interface, adhere to the following guidelines.

### JTAG Pin Connections

</tr>
<tr>
<td>3</td>
<td></td>
<td>Pull the TMS and TDI pins high through a resistor.</td>
</tr>
</tbody>
</table>

A device operating in JTAG mode uses four required pins—TDI, TDO, TMS, and TCK. The TCK pin has an internal weak pull-down resistor, while the TDI and TMS pins have weak internal pull-up resistors.

If you have more than one device in the chain, connect the TDO pin of a device to the TDI pin of the next device in the chain.

Noise on the JTAG pins during configuration, user mode, or power-up can cause the device to go into an undefined state or mode.

</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td>Ensure the download cable and JTAG pin voltages are compatible because the download cable interfaces with the JTAG pins of your device.</td>
</tr>
</tbody>
</table>

The operating voltage supplied to the Intel download cable by the target board through the 10-pin header determines the operating voltage level of the download cable.

JTAG pins in the Intel Stratix 10 device are powered up by $V_{CCIO_{-SDM}}$. In a JTAG chain containing devices with different $V_{CCIO}$ levels, ensure that the $V_{IL}$ max, $V_{IH}$ min, and the maximum $V_I$ specifications of the device JTAG input pins are not violated. Level shifter might be required between devices to meet the voltage specifications of the devices input pin.

### JTAG Signal Buffering

</tr>
<tr>
<td>2</td>
<td></td>
<td>If your device is in a configuration chain, ensure all devices in the chain are connected properly.</td>
</tr>
</tbody>
</table>
You might have to add buffers to a JTAG chain, depending on the JTAG signal integrity, especially the TCK signal, because it is the JTAG clock and the fastest switching JTAG signal. Intel recommends buffering the signals at the connector because cables and board connectors tend to make bad transmission lines and introduce noise to the signals. After this initial buffer at the connector, add buffers as the chain gets longer or whenever the signals cross a board connector.

If a cable drives three or more devices, buffer the JTAG signal at the cable connector to prevent signal deterioration. This also depends on the board layout, loads, connectors, jumpers, and switches on the board. Anything added to the board that affects the inductance or capacitance of the JTAG signals increases the likelihood that a buffer should be added to the chain.

Each buffer should drive no more than eight loads for the TCK and TMS signals, which drive in parallel. If jumpers or switches are added to the path, decrease the number of loads.

<td>Connect the SDM pins with MSEL function to select the configuration scheme; do not leave them floating. Do not hardwire the pins to VCCIO_SDM or GND if they have other configuration functions based on the configuration scheme selected.</td>
</tr>
</tbody>
</table>

Select the configuration scheme by pulling the SDM pins with MSEL function high or low with external resistors. JTAG configuration is always available, regardless of the MSEL settings. The SDM pins with MSEL function are powered by the VCCIO_SDM power supply, and they have internal weak pull-up resistors.

During POR and reconfiguration, the SDM pins with MSEL function must be at LVTTL $V_{IL}$ and $V_{IH}$ levels to be considered as logic low and logic high, respectively. The SDM pins used for MSEL function also have other configuration functions, depending on the configuration schemes used. Do not hardwire the SDM pins with MSEL function to VCCIO_SDM or GND without pull-up or pull-down resistors, if they are needed for the configuration scheme used.

Most of the SDM pins have multiple configuration functions, depending on the configuration schemes used. Some SDM pins also have power management functions. If power management function is required, choose the SDM pins which do not need to be used for configuration to implement the power management function.

Connect the SDM pins on your board to the external configuration host or configuration device based on the configuration scheme to be used. If more than one configuration scheme are used, ensure there is no contention between configuration host or configuration devices connected to the SDM pins.

<tr>
<td>2</td>
<td></td>
<td>Carefully check the pin connections in the Intel Quartus Prime software-generated .pin file. Do not connect RESERVED pins.</td>
</tr>
</tbody>
</table>

You can specify the state of unused pins in the Intel Quartus Prime software to allow flexibility in the board design by choosing one of the five allowable states for Reserve all unused pins on the Unused Pins category in the Device and Pin Options dialog box:

- As inputs tri-stated
- As output driving ground
- As outputs driving an unspecified signal
- As input tri-stated with bus-hold circuitry
- As input tri-stated with weak pull-up

The common setting is to set unused pins As inputs tri-stated with weak pull-up. To improve signal integrity, set the unused pins to As output driving ground. Doing this reduces inductance by creating a shorter return path and reduces noise on the neighboring I/Os. This approach should not be used if this results in many via paths causing congestion for signals under the device.

To reduce power dissipation, set clock pins and other unused I/O pins As inputs tri-stated, and tie them to ground.

Signal Integrity Considerations

Signal integrity considerations include detailed board design guidelines, as well as a few guidelines related to VREF pins, SSN, and I/O termination.

SSN is a concern when too many pins (in close proximity) change voltage levels at the same time. Noise generated by SSN can reduce the noise margin and cause incorrect switching. Although SSN is dominant on the device package, plan the board layout according to the board layout recommendations in the PCB guidelines can help with noise reduction.

Voltage-referenced I/O standards require both an $V_{REF}$ and a termination voltage ($V_{TT}$). The reference voltage of the receiving device tracks the termination voltage of the transmitting device. Each voltage-referenced I/O standard requires a unique termination setup.

Although single-ended, non-voltage-referenced I/O standards do not require termination, impedance matching is necessary to reduce reflections and improve signal integrity.

Intel Stratix 10 on-chip series and parallel termination provides the convenience of no external components. Alternatively, you can use external pull-up resistors to terminate the voltage-referenced I/O standards such as SSTL and HSTL.

Differential I/O standards typically require a termination resistor between the two signals at the receiver. The termination resistor must match the differential load impedance of the signal line. Intel Stratix 10 devices provide an optional on-chip differential resistor when using LVDS.

To ensure that the I/O signaling meets receiver threshold levels on your board setup, perform full board routing simulation with third-party board-level simulation tools using an IBIS model.

When this feature is available in the Intel Quartus Prime software, select IBIS under Board-level signal integrity analysis on the Board-Level page in EDA Tool Settings of the Settings dialog box.
When you include an FPGA device with high-speed interfaces in a board design, knowing the signal integrity and board routing propagation delay is vital for proper system operation. You should analyze board level timing as part of the I/O and board planning, especially for high-speed designs.

You can configure board trace models of selected I/O standards and generate "board-aware" signal integrity reports with the Intel Quartus Prime software. When Enable Advanced I/O Timing is turned on (Timing Analyzer page in the Settings dialog box), the Timing Analyzer uses simulation results for the I/O buffer, package, and the board trace model to generate more accurate I/O delays and extra reports to give insight into signal behavior at the system level. You can use these advanced timing reports as a guide to make changes to the I/O assignments and board design to improve timing and signal integrity.

**I/O and Clock Planning**

Planning and allocating I/O and clock resources is an important task with the high pin counts and advanced clock management features in Intel Stratix 10 devices. Various considerations are important to effectively plan the available I/O resources to maximize utilization and prevent issues related to signal integrity. Good clock management systems are also crucial to the performance of an FPGA design.

The I/O and clock connections of your FPGA affect the rest of your system and board design, so it is important to plan these connections early in your design cycle.

With the Intel Quartus Prime Pin Planner GUI, you can identify I/O banks, \texttt{VREF} groups, and differential pin pairings to help you through the I/O planning process. Right-click in the Pin Planner spreadsheet interface and click the **Pin Finder** to search for specific pins. If migration devices are selected, the Pin Migration view highlights pins that change function in the migration device when compared to the currently selected device.
You have the option of importing a Microsoft Excel spreadsheet into the Intel Quartus Prime software to start the I/O planning process if you normally use a spreadsheet in your design flow. You can also export a spreadsheet compatible (.csv) file containing your I/O assignments when all pins are assigned.

When you compile your design in the Intel Quartus Prime software, I/O Assignment Analysis in the Fitter validates that the assignments meet all the device requirements and generates messages if there are any problems.

Intel Quartus Prime designers can then pass the pin location information to PCB designers. Pin assignments between the Intel Quartus Prime software and your schematic and board layout tools must match to ensure the design works correctly on the board where it is placed, especially if changes to the pin-out must be made. The Pin Planner is integrated with certain PCB design EDA tools and can read pin location changes from these tools to check the suggested changes. When you compile your design, the Intel Quartus Prime software generates the .pin file. You can use this file to verify that each pin is correctly connected in the board schematics.

In many design environments, FPGA designers want to plan top-level FPGA I/O pins early so that board designers can start developing the PCB design and layout. The FPGA device’s I/O capabilities and board layout guidelines influence pin locations and other types of assignments. In cases where the board design team specifies an FPGA pin-out, it is crucial that you verify pin locations in the FPGA place-and-route software as soon as possible to avoid board design changes.
Starting FPGA pin planning early improves the confidence in early board layouts, reduces the chance of error, and improves the design’s overall time to market. You can create a preliminary pin-out for an Intel FPGA using the Intel Quartus Prime Pin Planner before the source code is designed.

Early in the design process, the system architect typically has information about the standard I/O interfaces (such as memory and bus interfaces), IP cores to be used in the design, and any other I/O-related assignments defined by system requirements.

The Pin Planner Create/Import IP Core feature interfaces with the IP catalog, and enables you to create or import custom IP cores that use I/O interfaces. Enter PLL and LVDS blocks, including options such as dynamic phase alignment (DPA), because options affect the pin placement rules. When you have entered as much I/O-related information as possible, generate a top-level design netlist file using the **Create Top-Level Design File** command in the Pin Planner. You can use the I/O analysis results to change pin assignments or IP parameters and repeat the checking process until the I/O interface meets your design requirements and passes the pin checks in the Intel Quartus Prime software.

When planning is complete, the preliminary pin location information can be passed to PCB designers. When the design is complete, use the reports and messages generated by the Intel Quartus Prime Fitter for the final sign-off of the pin assignments.

Intel Stratix 10 I/O pins are designed for ease of use and rapid system integration, while simultaneously providing high bandwidth. Independent modular I/O banks with a common bank structure for vertical migration lend efficiency and flexibility to the high speed I/O.

</tr>
</tbody>
</table>
Intel Stratix 10 devices support a wide range of industry I/O standards, including single-ended, voltage-referenced single-ended, and differential I/O standards. Follow these general guidelines when you select a signaling type.

Single-ended I/O signaling provides a simple rail-to-rail interface. Its speed is limited by the large voltage swing and noise. Single-ended I/Os do not require termination, unless reflection in the system causes undesirable effects.

Voltage-referenced signaling reduces the effects of simultaneous switching outputs (SSO) from pins changing voltage levels at the same time (for example, external memory interface data and address buses). Voltage-referenced signaling also provides an improved logic transition rate with a reduced voltage swing, and minimizes noise caused by reflection with a termination requirement. However, additional termination components are required for the reference voltage source ($V_{TT}$).

Differential signaling eliminates the interface performance barrier of single-ended and voltage-referenced signaling, with superior speed using an additional inverted closely-coupled data pair. Differential signaling also avoids the requirement for a clean reference voltage. This is possible because of a lower swing voltage and noise immunity with a common mode noise rejection capability. Considerations for this implementation include the requirements for a dedicated PLL to generate a sampling clock, and matched trace lengths to eliminate the phase difference between an inverted and non-inverted pair.

Intel Stratix 10 I/O pins are organized in pairs to support differential standards. Each I/O pin pair can support differential input or output operations, with the exception of certain clock pins that support differential input operations only. In your design source code, define just one pin to represent a differential pair, and make a pin assignment for this positive end of the pair. When you specify a differential I/O standard, the Intel Quartus Prime software automatically places the corresponding negative pin.

</tr>
</tbody>
</table>

Intel Stratix 10 I/O pins are arranged in groups called modular I/O banks. Be sure to use the correct dedicated pin inputs for signals such as clocks and global control signals.
The board must supply each bank with one \( V_{CCIO} \) voltage level for every \( V_{CCIO} \) pin in a bank. Each I/O bank is powered by the \( V_{CCIO} \) pins of that particular bank, and is independent of the \( V_{CCIO} \) pins of other I/O banks. A single I/O bank supports output signals that are driving at the same voltage as the \( V_{CCIO} \). An I/O bank can simultaneously support any number of input signals with different I/O standards.

To accommodate voltage-referenced I/O standards, each I/O bank supports multiple \( V_{REF} \) pins feeding a common \( V_{REF} \) bus. Set the \( V_{REF} \) pins to the correct voltage for the I/O standards in the bank. Each I/O bank can only have a single \( V_{CCIO} \) voltage level and a single \( V_{REF} \) voltage level at a given time. If the \( V_{REF} \) pins are not used as voltage references, they cannot be used as generic I/O pins and should be tied to \( V_{CCIO} \) of that same bank or GND.

An I/O bank including single-ended or differential standards can support voltage-referenced standards as long as all voltage-referenced standards use the same \( V_{REF} \) setting. Voltage-referenced bi-directional and output signals must drive out at the I/O bank’s \( V_{CCIO} \) voltage level.

Different I/O banks include different support for LVDS signaling, and the Intel Stratix 10 transceiver banks include additional support. There are two types of I/O banks, LVDS and 3 V.

The LVDS I/O bank supports differential and single-ended I/O standards up to 1.8 V. The LVDS I/O pins form pairs of true differential LVDS channels. Each pair supports a parallel input/output termination between the two pins. You can use each LVDS channel as transmitter or receiver.

The 3 V I/O bank supports only single-ended I/O standards up to 3 V. Each adjacent I/O pair also supports Differential SSTL and Differential HSTL I/O standards. The single-ended output of the 3 V I/O has the same set of features as the single-ended output of the DDR I/O IP, except the programmable pre-emphasis feature.

Intel Stratix 10 devices provide an efficient architecture to quickly and easily fit wide external memory interfaces with their small modular I/O banks. The Intel Stratix 10 FPGA can support DDR external memory on any I/O banks on all sides of the device that do not support transceivers.

The self-calibrating External Memory Interfaces IP core is optimized to take advantage of the Intel Stratix 10 I/O structure. The External Memory Interfaces IP core allows you to set external memory interface features and helps set up the physical interface (PHY) best suited for your system. When you use the Intel memory controller Intel FPGA IP functions, the External Memory Interfaces IP core is instantiated automatically. If you design multiple memory interfaces into the device using Intel FPGA IP core, generate a unique interface for each instance to ensure good results instead of designing it once and instantiated it multiple times.

The data strobe DQS and data DQ pin locations are fixed in Intel Stratix 10 devices. Before you design your device pin-out, refer to the memory interface guidelines for details and important restrictions related to the connections for these and other memory-related signals.

You can implement a protocol that is not supported by External Memory Interfaces IP core by using the PHY Lite for Parallel Interfaces Intel Stratix 10 FPGA IP core.

Address and command pins within the address/command bank must follow a fixed pin-out scheme, as defined in the <variation_name>_readme.txt file generated with your IP core. The pin-out scheme varies according to the topology of the memory interface. The pin-out scheme is a hardware requirement that you must follow. Some schemes require three lanes to implement address and command pins, while others require four lanes.

Intel Stratix 10 devices allow I/O flexibility with dual-purpose configuration pins. You can use dual-purpose configuration pins as general I/Os after device configuration is complete. Select the desired setting for each of the dual-purpose pins on the Dual-Purpose Pins category of the Device and Pin Options dialog box. Depending on the configuration scheme, these pins can be reserved as regular I/O pins, as inputs that are tri-stated, as outputs that drive ground, or as outputs that drive an unspecified signal.
You can also use dedicated clock inputs, which drive the programmable clock routing networks, as general-purpose input pins if they are not used as clock pins. When you use the clock inputs as general inputs, I/O registers use ALM-based registers because the clock input pins do not include dedicated I/O registers.

The device-wide reset and clear pins are available as design I/Os if they are not enabled.

</tbody>
</table>

The first stage in planning your clocking scheme is to determine your system clock requirements. Understand your device's available clock resources and correspondingly plan the design clocking scheme. Consider your requirements for timing performance, and how much logic is driven by a particular clock.
Intel Stratix 10 devices provide dedicated low-skew and high fan-out routing networks.

The dedicated clock pins drive the clock network directly, ensuring lower skew than other I/O pins. Use the dedicated routing network to have a predictable delay with less skew for high fan-out signals. You can also use the clock pins and clock network to drive control signals like asynchronous reset.

Connect clock inputs to specific PLLs to drive specific low-skew routing networks. Analyze the global resource availability for each PLL and the PLL availability for each clock input pin.

Intel Stratix 10 devices contain dedicated resources for distributing signals throughout the fabric with balanced delay. These resources are typically used for clock signals. You can also use these resources for other signals with low-skew requirements. In Intel Stratix 10 devices, these resources are implemented as a programmable clock routing, which allows for the implementation of low-skew clock networks of variable size.

If your system requires more clock or control signals than are available in the target device, consider cases where the dedicated clock resource could be spared, particularly low fan-out and low-frequency signals where clock delay and clock skew do not have a significant impact on the design performance. Use the Global Signal assignment in the Intel Quartus Prime Assignment Editor to select the type of global routing, or set the assignment to Off to specify that the signal should not use any global routing resources.

Based on your system requirements, define the required clock frequencies for your FPGA design, and the input frequencies available to the FPGA. Use these specifications to determine your PLL scheme. Use the Intel Quartus Prime parameter editor to enter your settings in IOPLL Intel FPGA IP core, and check the results to verify whether particular features and input/output frequencies can be implemented in a particular PLL.

Intel Stratix 10 devices contain fractional PLLs in addition to I/O PLLs. You can configure fractional PLLs as integers or as enhanced fractional PLLs.

You can use I/O PLLs and fractional PLLs to reduce the number of oscillators required on the board, as well as to reduce the clock pins used in the FPGA by synthesizing multiple clock frequencies from a single reference clock source. In addition, you can use fractional PLLs for transmit clocking for transceivers.

Intel Stratix 10 device PLLs are feature rich, and support advanced capabilities such as clock feedback modes, switchover, and dynamic phase shifting.

In a synchronous design, a clock signal triggers all events. When all of the registers’ timing requirements are met, a synchronous design behaves in a predictable and reliable manner for all process, voltage, and temperature (PVT) conditions. You can easily target synchronous designs to different device families or speed grades.
Problems with asynchronous design techniques include reliance on propagation delays in a device, incomplete timing analysis, and possible glitches. Pay particular attention to your clock signals, because they have a large effect on your design’s timing accuracy, performance, and reliability. Problems with clock signals can cause functional and timing problems in your design. Use dedicated clock pins and clock routing for best results. For clock inversion, multiplication, and division, use the device PLLs. For clock multiplexing and gating, use the dedicated clock control block or PLL clock switchover feature instead of combinational logic. If you must use internally generated clock signals, register the output of any combinational logic used as a clock signal to reduce glitches. For example, if you divide a clock using combinational logic, clock the final stage with the clock signal that was used to clock the divider circuit.

Intel provides parameterizable IP cores that are optimized for Intel device architectures. You can save design time by using IP cores instead of coding your own logic. Additionally, the Intel-provided IP cores can offer more efficient logic synthesis and device implementation. You can scale the IP core's size and set various options with parameters. IP cores include the library of parameterized modules (LPM) and Intel device-specific IP cores. You can also take advantage of Intel and third-party IP cores and reference designs to save design time. The Intel Quartus Prime IP catalog provides a user interface to customize IP cores. You should build or change IP core parameters using the parameter editor to ensure you set all ports and parameters correctly.

Intel Stratix 10 devices allow you to easily modify your transceivers and FPGA-core while other portions of your design are still running by using dynamic reconfiguration and partial reconfiguration, respectively.
Intel Stratix 10 devices allow you to dynamically reconfigure different portions of the transceivers for different protocols, data rates, and PMA settings without powering down any part of the device or interrupting adjacent transceiver channels. This feature will be available in a future release of the Intel Quartus Prime software.

If you are interested in using partial reconfiguration, contact your local Intel representatives for support.

**Design Implementation, Analysis, Optimization, and Verification**

After you create your design source code and apply constraints including the device selection and timing requirements, your synthesis tool processes the code and maps it to elements of the device architecture. The Intel Quartus Prime Fitter then performs placement and routing to implement the design elements in specific device resources. If required, you can use the Intel Quartus Prime software to optimize the design’s resource utilization and achieve timing closure, preserve the performance of unchanged design blocks, and reduce compilation time for future iterations. You can also verify the design functionality with simulation. This section provides guidelines for these stages of the compilation flow.

The Intel Quartus Prime software includes advanced and easy-to-use integrated synthesis that fully supports Verilog HDL and VHDL, as well as the Intel hardware description language (AHDL) and schematic design entry. You can also use industry-leading third-party EDA synthesis tools to synthesize your Verilog HDL or VHDL design, and then compile the resulting output netlist file in the Intel Quartus Prime software. Specify a third-party synthesis tool in the New Project Wizard or the EDA Tools Settings page of the Settings dialog box to use the correct Library Mapping File (.lmf) for your synthesis netlist.

Intel recommends using the most recent version of third-party synthesis tools, because tool vendors are continuously adding new features, fixing tool issues, and enhancing performance for Intel devices.

Different synthesis tools can give different results. If you want to select the best-performing tool for your application, you can experiment by synthesizing typical designs for your application and coding style and comparing the results. Be sure to perform placement and routing in the Intel Quartus Prime software to get accurate timing analysis and logic utilization results.

Your synthesis tool might offer the capability to create a Intel Quartus Prime project and pass constraints such as the EDA tool setting, device selection, and timing requirements that you specified in your synthesis project. You can use this capability to save time when setting up your Intel Quartus Prime project for placement and routing.

After compilation in the Intel Quartus Prime software, review the device resource utilization information to determine whether the future addition of extra logic or other design changes introduce fitting difficulties. If your compilation results in a no-fit error, resource utilization information is important so you can analyze the fitting problems in your design.
To determine resource usage, refer to the Flow Summary section of the Compilation Report for a percentage representing the total logic utilization, which includes an estimation of resources that cannot be used due to existing connections or logic use.

For Intel Stratix 10 devices, low logic utilization does not have the lowest ALM utilization possible. In addition, a design that is reported as close to 100% full might still have space for extra logic. The Fitter uses ALUTs in different ALMs, even when the logic can be placed within one ALM, so that it can achieve the best timing and routability results. Logic might be spread throughout the device when achieving these results. As the device fills up, the Fitter automatically searches for logic that can be placed together in one ALM.

More detailed resource information is available by viewing the reports under Fitter ➤ Place section of the Compilation Report. The Fitter Resource Usage Summary report breaks down the logic utilization information and indicates the number of fully and partially used ALMs, and provides other resource information including the number of bits in each type of memory block. There are also reports that describe some of the optimizations that occurred during compilation. For example, if you use the Intel Quartus Prime integrated synthesis, the reports under Analysis & Synthesis ➤ Partition <partition_name> ➤ Optimization Results provide information, including registers that were removed during synthesis. Use this report to estimate device resource utilization for a partial design to ensure that registers were not removed due to missing connections with other parts of the design.

</tr>
</tbody>
</table>
In an FPGA design flow, accurate timing constraints allow timing-driven synthesis software and place-and-route software to obtain optimal results. Timing constraints are critical to ensure designs meet their timing requirements, which represent actual design requirements that must be met for the device to operate correctly. The Intel Quartus Prime software optimizes and analyzes your design using different timing models for each device speed grade, so you must perform timing analysis for the correct speed grade. The final programmed device might not operate as expected if the timing paths are not fully constrained, analyzed, and verified to meet requirements.

The Intel Quartus Prime software includes the Intel Quartus Prime Timing Analyzer, a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design. It supports the industry standard Synopsys* Design Constraints (SDC) format timing constraints, and has an easy-to-use GUI with interactive timing reports. It is ideal for constraining high-speed source-synchronous interfaces and clock multiplexing design structures.

A comprehensive static timing analysis includes analysis of register to register, I/O, and asynchronous reset paths. It is important to specify the frequencies and relationships for all clocks in your design. Use input and output delay constraints to specify external device or board timing parameters. Specify accurate timing requirements for external interfacing components to reflect the exact system intent.

The Timing Analyzer performs static timing analysis on the entire system, using data required times, data arrival times, and clock arrival times to verify circuit performance and detect possible timing violations. It determines the timing relationships that must be met for the design to correctly function.

You can use the `report_datasheet` command to generate a datasheet report that summarizes the I/O timing characteristics of the entire design.

These assignments and settings are important for large designs such as those in Intel Stratix 10 devices.

When you turn on the **Optimize multi-corner timing** option, the design is optimized to meet its timing requirements at all timing process corners and operating conditions. Therefore, turning on this option helps create a design implementation that is more robust across PVT variations.

This section highlights some of the features offered in the Intel Quartus Prime software to help optimize area (or resource utilization) and timing performance. If the timing analysis reports that your design requirements were not met, you must make changes to your design or settings and recompile the design to achieve timing closure. If your compilation results in no-fit messages, you must make changes to get successful placement and routing.

You can run Fitter (Plan) to estimate your design’s timing results before the software performs full placement and routing. Click **Processing ➤ Start ➤ Start Fitter (Plan)** to generate initial compilation results after you have run analysis and synthesis.

Physical synthesis optimizations make placement-specific changes to the netlist that improve results for a specific Intel device. You can optimize for performance and fitting in the **Physical Synthesis Optimizations** page of the **Settings** dialog box. The options in the **Physical Synthesis Optimizations** page typically increase compilation time significantly but can provide significant improvements to the quality of results with push-button optimizations. If you turn on these options, ensure that they do improve the results for your design. If you do not require these options to meet your design timing requirements, turn off the options to reduce the compilation time.

The Design Space Explorer II (DSE II) is a utility that automates the process to find optimal project settings for resource, performance, or power optimization goals. DSE II attempts multiple seeds to identify one that meets your requirements. The **Exploration Panel ➤ Exploration mode** allows you a predefined exploration space to target design performance, area of improvements, or power reduction with multiple compilations.
The Optimization Advisors provide guidance in making settings that optimize your design. On the Tools menu, click Advisor ➤ Timing Optimization Advisor. Evaluate the options and choose settings that suit your requirements.

Use the incremental compilation feature to preserve logic in unchanged parts of your design, preserve timing performance, and reach timing closure more efficiently. You can speed up design iteration time by an average of 60% when making changes to the design with the incremental compilation feature.

The Intel Quartus Prime software can run some algorithms in parallel to take advantage of multiple processors and reduce compilation time when more than one processor is available to compile the design. Set the Parallel compilation option on the Compilation Process Settings page of the Settings dialog box, or change the default setting in the Options dialog box in the Processing page from the Tools menu.

The Compilation Time Advisor provides guidance in making settings that reduce your design compilation time. On the Tools menu, point to Advisors and click Compilation Time Advisor. Using some of these techniques to reduce compilation time can reduce the overall quality of results.

The Intel Quartus Prime software supports both RTL and gate level functional simulations. Perform functional simulation at the beginning of your design flow to check the design functionality or logical behavior of each design block. You do not have to fully compile your design; you can generate a functional simulation netlist that does not contain timing information.

Intel provides the ModelSim* - Intel FPGA Starter Edition and offers the higher performance ModelSim - Intel FPGA Edition, which enable you to take advantage of advanced testbench capabilities and other features. In addition, the Intel Quartus Prime EDA Netlist Writer can generate timing netlist files to support other third-party simulation tools such as Synopsys VCS, Cadence NC-Sim, and Aldec Active-HDL. Specify your simulation tool in the EDA Tools Settings page of the Settings dialog box to generate the appropriate output simulation netlist.

If you use a third-party simulation tool, use the software version that is supported with your Intel Quartus Prime software version. The Intel Quartus Prime Software Release Notes list the version of each simulation tool that is officially supported with that particular version of the Intel Quartus Prime software. Use the model libraries provided with your Intel Quartus Prime software version, because libraries can change between versions, which might cause a mismatch with your simulation netlist. </tr>
</tbody>
</table>

Before design completion, estimate power consumption using the EPE spreadsheet. After compiling your design, analyze the power consumption and heat dissipation with the Intel Quartus Prime Power Analyzer to ensure the design has not violated power supply and thermal budgets.

You must compile a design (to provide information about design resources, placement and routing, and I/O standards) and provide signal activity data (toggle rates and static probabilities) to use the Power Analyzer. You can derive signal activity data from simulation results or a user-defined default toggle rate and vectorless estimation. The signal activities used for analysis must be representative of the actual operating behavior. For the most accurate power estimation, use gate-level simulation results with a .vcd output file from a third-party simulation tool. The simulation activity should include typical input vectors over a realistic time period and not the corner cases often used during functional verification. Use the recommended simulator settings (such as glitch filtering) to ensure good results.

You must also specify operating conditions, including the core voltage, device power characteristics, ambient and junction temperature, cooling solution, and the board thermal model. Select the appropriate settings on the Operating Settings and Conditions page in the Settings dialog box.

To calculate the dynamic, static, and I/O thermal power consumption, on the Processing menu, click Power Analyzer Tool. The tool also provides a summary of the signal activities used for analysis and a confidence metric that reflects the overall quality of the data sources for signal activities.

The report is a power estimate based on the data provided, and is not a power specification. Always refer to the datasheet for the power specification of your device.

Clocks represent a significant portion of dynamic power consumption, because of their high switching activity and long paths. The Intel Quartus Prime software automatically optimizes clock routing power by enabling only the portions of a clock network that are required to feed downstream registers. You can also use clock control features to
dynamically enable or disable the clock network. When a clock network is powered down, all the logic fed by that clock network does not toggle, thereby reducing the overall power consumption of the device.

To reduce LAB-wide clock power consumption without disabling the entire clock tree, use the LAB-wide clock enable signal to gate the LAB-wide clock. The Intel Quartus Prime software automatically promotes register-level clock enable signals to the LAB level.

The dynamic power consumed in the I/O buffer is proportional to the total load capacitance; therefore, lower capacitance reduces power consumption.

Non-terminated I/O standards such as LVTTL and LVCMOS have a rail to-rail output swing equal to the \( \text{V}_{\text{CCIO}} \) supply voltage. Because dynamic power is proportional to the square of the voltage, use lower voltage I/O standards to reduce dynamic power. These I/O standards consume little static power.

Because dynamic power is also proportional to the output transition frequency, use resistively-terminated I/O standards such as SSTL for high-frequency applications. The output load voltage swings by an amount smaller than the \( \text{V}_{\text{CCIO}} \) around a bias point; therefore, dynamic power is lower than for non-terminated I/O under similar conditions.

Resistively-terminated I/O standards dissipate significant static power because current is constantly driven into the termination network. Use the lowest drive strength that meets your speed and waveform requirements to minimize static power when using resistively terminated I/O standards.
The power used by external devices is not included in the EPE calculations, so be sure to include it separately in your system power calculations.

                  • Updated the Design Assistant in the Design Recommendations section.  
                  • Updated the Reconfiguration section.  
                  • Removed information on formal verification in the Design Implementation, Analysis, Optimization, and Verification section.  
                  • Updated report locations in the Device Resource Utilization Reports section.  
                  • Updated the Timing Constraints and Analysis section.

| February 2017 | 2017.02.13 | • Updated the Recommended Timing Optimization and Analysis Assignments Checklist table.  
  — Removed checklist item on derive_pll_clocks.  
  — Added checklist item on set_false_path and set_clock_groups.  
• Updated the Area and Timing Optimization section.  
• Updated description on Hyper-Registers in the Designing with Intel HyperFlex section.  
• Removed information on NativeLink in the Simulation section.  
• Removed information on programmable power tiles in the following section:  
  — Power Optimization  
  — Device Speed Grade  
  — Intel Quartus Prime Power Optimization Techniques  
• Removed the following sections:  
  — Device-Wide Output Enable Pin  
  — Register Power-Up Levels and Control Signals  
  — Formal Verification  
• Updated the following terms:  
  — Changed Qsys to Platform Designer  
  — Changed OpenCore Plus to Intel FPGA IP Evaluation Mode  
  — Changed TimeQuest Timing Analyzer to Timing Analyzer  
  — Changed BluePrint Platform Designer to Interface Planner  
• Updated IP name from Altera PHYLite for Parallel Interfaces to PHY Lite for Parallel Interfaces.  
• Rebranded as Intel.  

| October 2016 | 2016.10.31 | Initial release.                                                                                                                          |
